To the Editor-In-Chief,  
*Heliyon*

**SUBMISSION OF MANUSCRIPT FOR PUBLICATION**

We herein submit our manuscript entitled “**SARS-CoV-2 Genomic Surveillance and Reliability of PCR Single Point Mutation Assay (SNPsig®EscapePLEX) for the Rapid Detection of Variants of Concern in Cameroon**”, for publication in **Journal of Virological Methods**.

With the rapid spread and evolution of SARS-CoV2 preoccupying variants of concern (Alpha, Beta, Gamma, Delta, Omicron), countries all over the globe have set-up various ranges of tools and public approaches to adequately respond to the pandemic. Our manuscript hereby present results from a simplified genotyping kit based on qPCR-multiplex approach, implemented in Cameroon as an alternative to high throughput sequencing, and developed to increase the feasibility and efficiency of genomic surveillance of SARS-CoV-2 variants in low and middle income countries. In the frame of the genomic surveillance of SARS-CoV-2 in Cameroon, our objective was to describe the SARS-CoV-2 dynamics across epidemiological waves and evaluate the reliability of SNP EscapePLEX-kit in detecting all variants of concerns. Sharing this evidence with readers of the **Diagnostic Microbiology & Infectious Disease** (clinicians, virologists and policies-makers) will contribute substantially in limiting the spread and adequately framing the response against SARS-CoV2 not just across other resource-limited settings, but even beyond.

The manuscript has not been submitted and is not under consideration elsewhere. All authors approved this final version.

Thank you in advance for your time and attention, and we hope that our manuscript will be deemed acceptable for publication in the *Heliyon* .

Cordially yours,

**Dr Joseph Fokam**

34 **Abstract**

1  
2  
3 35 **Background:** Surveillance of SARS-CoV-2 variants of concern (VOC) and lineages is  
4 36 crucial for decision-making. Our objective was to study the SARS-CoV-2 clade dynamics  
5 37 across epidemiological waves and evaluate the reliability of SNP EscapePLEX-kit in  
6  
7 38 detecting VOC in Cameroon.

8  
9 39 **Material and Methods:** A laboratory-based study was conducted on SARS-CoV-2 positive  
10 40 nasopharyngeal specimens (Ct-value<30) at the Chantal BIYA International Reference Centre  
11 41 in Yaoundé-Cameroon, between April-2020 to August-2022. For each sample, Sanger-  
12 42 sequencing and SNP-EscapePLEX-kit were performed, using sequencing as gold standard to  
13 43 evaluate the performance of SNP-EscapePLEX.

14  
15  
16 44 **Results:** Of the 130 sequences generated, SARS-CoV-2 clades during wave-1 (April-  
17 45 November 2020) showed 97%(30/31) wild-type lineages and 3%(1/31) Gamma-variant;  
18 46 wave-2 (December-2020 to May-2021), 25%(4/16) Alpha-variant, 25%(4/16) Beta-variant,  
19 47 44%(7/16) wild-type and 6%(1/16) mu; wave-3 (June-October 2021), 94%(27/29) Delta-  
20 48 variant, 3%(1/29) Alpha-variant, 3%(1/29) wild-type; wave-4 (November-2021 to August-  
21 49 2022), 98%(53/54) Omicron-variant and 2%(1/54) Delta-variant. Omicron sub-variants were  
22 50 BA.1(47%), BA.5(34%), BA.2(13%) and BA.4(6%). Overall sensitivity and specificity of  
23 51 *SNP-Escaplex* was 84%[78-87] and 89%[76-95] respectively, with 75%[63-76] and 100%[96-  
24 52 100] respectively for Delta-variant; and 96%[90-96] and 100%[93-100] for Omicron-variants.

25  
26  
27 53 **Conclusion:** Genomic surveillance reveals a rapid dynamic in SARS-CoV-2 strains between  
28 54 epidemiological waves in Cameroon. For wide variant surveillance in resource-limited  
29 55 settings, EscapePLEX-kit represents a suitable tool, pending upgrading for distinguishing  
30 56 Omicron sub-lineages.

1 **59 1 Introduction**

2  
3 60 Coronavirus disease 2019 (COVID-19), caused by the severe acute respiratory  
4  
5 61 syndrome coronavirus-2 (SARS-CoV-2), has spread worldwide with several implications  
6  
7  
8 62 (Chen et al., 2020). In Africa, 53 countries have been affected so far, with 12,059,691  
9  
10 63 confirmed cases (with 255,698 deaths and 11,433,772 recoveries ) (PHEOCC, 2022). In  
11  
12  
13 64 Cameroon, the first case of SARS-CoV-2 detection was reported on 6 March 2020. The  
14  
15 65 infection then spread rapidly and nationwide, with up to 123 480 confirmed cases, 1 957  
16  
17  
18 66 deaths, 120 773 recoveries (recovery rate: 97.8%), and 1 561 462 people received at least one  
19  
20 67 dose of vaccine (Ministry of Public Health, 2022). Alongside these figures, with anecdotal  
21  
22  
23 68 clinical implications, SARS-CoV-2 variants of concern (VOC) have emerged and circulated  
24  
25 69 around the world (Gabutti et al., 2020; Sanyaolu et al., 2021).

26  
27  
28 70 On 11 May 2021, the World Health Organisation (WHO) designated four different  
29  
30  
31 71 VOCs, including the B.1.1.7 (Alpha lineage ; UK in September 2020), B.1.351 (Beta lineage ;  
32  
33 72 South Africa in May 2020), P.1 (Gamma lineage; Brazil in November 2020) et B.1.617.2  
34  
35 73 (Delta lineage ; India in October 2020) (WHO, 2021).WHO designated the Pango B.1.1.529  
36  
37  
38 74 line as Omicron (first case reported from South Africa, in November 2021), a VOC which has  
39  
40  
41 75 spread rapidly around the world (Weil et al., 2022). Each of these VOCs is characterized by a  
42  
43 76 combination of mutations, some of which may also increase the virulence of SARS-CoV-2  
44  
45 77 and its ability to evade vaccines or other social and public health measures (WHO,  
46  
47  
48 78 2021).During the SARS-CoV-2 pandemic, genomic epidemiological surveillance around the  
49  
50 79 world became crucial to monitoring the emergence of new variants. Current methods for the  
51  
52  
53 80 detection and characterisation of SARS-CoV-2 variants including: Next generation  
54  
55 81 sequencing (NGS), Spike gene Sanger-based sequencing and screening SNP (Single nucleotide  
56  
57  
58 82 polymorphism) assays. The NGS essay is the gold standard for the identification of SARS-  
59  
60 83 CoV-2 variants. However, this technique requires quite a lot of time to implement and is not  
61  
62  
63  
64  
65

84 financially accessible for resource-limited settings (RLS) (Pennell et al., 2019; Pereira et al.,  
85 2020). Beside a well implemented Sanger sequencing approach (notably through Homemade  
86 protocols), PCR Point Mutation Assay (SNPsig®EscapePLEX) can be an alternative for the  
87 identification of VOCs, as it can provide very fast results with less consumables and reagents.  
88 Of note, scientific evidence shows that the Sanger method is very advantageous in terms of  
89 analysis time (15 hours for Sanger sequencing versus 51 hours for NGS) and cost per sample  
90 (20 times lower for Sanger sequencing) (Dorlass et al., 2021).

91 For rapid interventions in response to the evolution of SARS-CoV-2 variants,  
92 Cameroon has acquired a simplified genotyping kit, SNPsig®EscapePLEXsig of the  
93 "NOVACYT GROUP" company ([www.novacyt.com](http://www.novacyt.com)). This kit was developed to increase the  
94 feasibility and efficiency of genomic surveillance of SARS-CoV-2 variants in low and middle  
95 income countries (LMIC) as an alternative to sequencing method. The SNPsig®-SARS-CoV-  
96 2-EscapePLEX assay is a new product designed for in vitro molecular diagnostics for allelic  
97 discrimination of SARS-CoV-2 VOCs. The procedure follows the standard real-time PCR  
98 method. This multiplex qPCR typing method allows discriminatory and simultaneous  
99 identification of four clinically significant mutations in the SARSCoV-2 Spike genome:  
100 E484K, K417N, K417T et P681R (NOVACYT, 2021). However, it is important to note that  
101 existing SNP assays may fail to detect or identify newly emerging variants that do carry a  
102 specific due to amino acid substitutions at sites affecting the primer/probe binding. Given the  
103 low-level of evidence on genomic surveillance of SARS-CoV-2 variants in RLS, and the need  
104 for SARS-CoV-2 rapid variant detection, it would be of paramount importance to understand  
105 the changes in circulating viral clades and their potential impacts on the performance of rapid  
106 variant detection assays available locally.

107 Within the frame of genomic surveillance, we therefore sought to study the dynamics  
1 of viral lineages/variants and to evaluate the performance of SNPsig®EscapePLEXsig kit as a  
2 108 of viral lineages/variants and to evaluate the performance of SNPsig®EscapePLEXsig kit as a  
3  
4 109 rapid point mutation assay for SARS-CoV-2 clade surveillance in RLS like Cameroon.  
5  
6  
7

## 8 110 **2 Materials and methods**

### 11 111 2.1 Study design

12 112 **Study type and population:** A laboratory-based study was conducted from April 2020  
13  
14  
15 113 throughout August 2022 on nasopharyngeal specimens of individuals confirmed positive to  
16  
17 114 COVID-19 by real-time PCR at the Virology Laboratory of the “Chantal BIYA” International  
18  
19  
20 115 Reference Centre in Yaoundé, Cameroon. Briefly, CIRCB a national reference laboratory for  
21  
22 116 SARS-CoV-2 molecular testing and a reference centre genomic surveillance at country-level.  
23  
24

25 117 **Clinical specimens:** The main criteria for sample selection were the mean of cycle threshold  
26  
27  
28 118 (Ct) value under 35 (ORF1ab, N genes; for *DaAnGene* RT-PCR assay).  
29  
30

### 31 119 2.2 Detection of SARS-CoV-2 VOC with Sanger Spike-sequencing

32 120 Following experience in Sanger sequencing protocol used as standard for viral  
33  
34  
35  
36 121 genotyping (Fokam et al., 2022, 2011; Takou et al., 2019), the protocol for sequencing of  
37  
38 122 SARS-CoV-2 was designed using new primers to amplify a fragment of the SARS-CoV-2  
39  
40  
41 123 genome encoding part of the Spike protein.  
42  
43

#### 44 124 2.2.1 RNA extraction:

45 125 Viral RNA was manually extracted from 200 µL nasopharyngeal clinical swabs samples using  
46  
47  
48 126 the *DaAnGene* viral RNA Mini kit according to the manufacturer’s protocol  
49  
50 127 ([www.daangene.com](http://www.daangene.com)). SARS-CoV-2 -RNA was then processed directly for conventional  
51  
52 128 reverse transcription and amplification.  
53  
54

#### 55 129 2.2.2 Reverse transcription and PCR amplification: 56 130

57  
58  
59  
60  
61  
62  
63  
64  
65

## *HELIYON*

131 Viral RNA was retro-transcribed and amplified using the kit One-Step Invitrogen  
132 (SuperScript® One-Step for long templates RT/ PCR; Foster City, CA) and 2 different  
133 sequence-specific primers (5'-3'): **38F** (-GTCAGTGTGTTAATCTTACAACCAG-) as the as the  
134 forward, and **1191R** (-TGCATAGACATTAGTAAAGCAGAGA-) as the reverse, (the given  
135 position refers to the Wuhan strain of SARS-CoV-2). The RT-PCR reaction contained for for  
136 each sample 25 µl reaction mix, 8 µl MgSO<sub>4</sub> (5 mM), 3 µl DNase- and RNase-free water,  
137 0.75 µl sense primer (10 mM stock), 0.75 µl antisense primer (10 mM stock), 1 µl  
138 RNaseOUT (5 U/ µl Invitrogen), 1.5 µl RT-Taq (Superscript III RT/Platinum high fidelity )  
139 and 10 µl of extracted RNA. The RT-PCR conditions consisted of an initial step of 1 cycle at  
140 50°C for 30 min; 1 cycle of 94°C for 2 min; 40 cycles (95°C, 30 s; 52°C, 30 s; 72°C, 90 s); a  
141 final elongation step of 1 cycle at 72°C for 10 min. The expected cDNA is about 1200 base  
142 pairs (bp)in length (position 38[orf]-1191 [orf]). For each PCR reaction, positive and negative  
143 controls were used to ensure the effectiveness of the reaction and the absence of cross-  
144 contamination, respectively. Amplification results were revealed after agarose-gel  
145 electrophoresis and positive results were kept for the sequencing process. Then PCR products  
146 were purified through the ExoSAP-IT™ kit (Applied Biosystems™, Lithuania).

### 2.2.3 Sequencing reaction (Sanger method):

149 The amplified products from the ORF region were completely sequenced in the sense and  
150 antisense orientations using an automated sequencer (ABI 3500 Genetic Ana- lyzer) with four  
151 different overlapping sequence-specific primers: **38F**,**514F**(TCTCAGCCTTTTCTTATGGACCT),  
152 **655R** (CCTGAGGGAGATCACGCACTA) and **1191F**. The reaction mixture for the sequencing  
153 reaction contained 1.5 µl ABI PRISM Big Dye Terminator V3.1, 6.5 µl big dye diluent (from  
154 the kit), 4.8 µl DNase/ RNase-free water water, 3.2 µl primer (1 µM stock) and 2 µl of purified  
155 cDNA .The sequencing conditions were as follows: 35 cycles (96°C, 10 s; 55°C, 10 s; 60°C, 4  
156 min); 1 cycle of 4°C for 30 min. The sequencing product was purified by gel filtration

157 chromatography using Sephadex G-50 resin (Sigma-Aldrich) in order to eliminate excess  
158 primers, unincorporated dideoxynucleotides (ddNTPs), and salts. Capillary electrophoresis  
159 was performed using an Applied Biosystems 3500 genetic analyzer (Applied Biosystems,  
160 Tokyo, Japan).

#### 2.2.4 SARS-CoV-2 sequence analysis

The sequences were aligned assembled and edited by the reference sequence using SeqScape Version 2.7. Spike Sequence were interpreted using the COV19 database Stanford algorithm (<https://covdb.stanford.edu>) and NCBI (National Center for biotechnology information). SARS-CoV-2 Spike gene nucleotide sequences were submitted to GenBank using Bankit (<https://www.ncbi.nlm.nih.gov/WebSub/>).

### 2.3 Detection of SARS-CoV-2 VOC with SNP genotyping

SNP genotyping reaction was performed using the commercial SNPsig® SARS-CoV-2 (EscapePLEX CE ) kit (PrimerDesign, UK); according to the manufacturer's protocol (PRIMER DESIGN, 2022). This kit can be used on any thermocycler able to detect fluorescence in **the FAM, HEX/VIC, ROX and Cy5** emission channels. The kit also includes primers for confirmation of a positive SARS-CoV-2 result. The kit contains all the necessary items to perform the test. The RT-qPCR reaction contained 5µL of RNA and 25ml of reaction mixture for each sample (10µL Master Mix OneStep, 1µL primers/probes, 4µL RNase/DNase free watter, un volume final de 15µL). After preparation of the reaction mixture for genotyping, the real-time PCR reaction was performed on a thermocycler (QuantStudio 7 Flex, Applied Biosystems, by thermos Fisher) according to the following program: reverse transcription for 10min at 55°C, enzyme activation for 2min at 95°C, 45 cycle of (denaturation for 10s at 95°C, hybridization and elongation for 60s at 60°C). Mutations and variants were interpreted according to the kit manufacturers' guidelines.

181 2.4 Data Analysis

1 182 Descriptive statistics were performed for socio-demographic data and clinical  
2  
3  
4 183 parameters wherever available. Median and interquartile range (IQR) were reported for  
5  
6 184 continuous variables. Chi-square ( $\chi^2$ ) and Fisher's exact test were used for comparison, and  
7  
8  
9 185 the significance level was set at  $P \leq 0.05$ . The SNP-ExcaPLEX kit sensitivity and specificity,  
10  
11 186 were computed with their 95% confidence interval (CI). Cohen's kappa was used to estimate  
12  
13  
14 187 inter-assay concordance and results were interpreted according to the criteria proposed by  
15  
16 188 Landis & Koch:  $k=0.01-0.20$  (poor concordance),  $k=0.21-0.40$  (fair concordance),  $k=0.41-$   
17  
18 189  $0.60$  (moderate concordance),  $k=0.61-0.80$  (strong concordance), and  $k=0.81-1.00$  (almost  
19  
20  
21 190 perfect concordance)(Jr and Gg, 1977). The status of the sample was defined as “true  
22  
23 191 positive”/”true negative” when sequencing data agreed with the results obtained with SNPsig  
24  
25  
26 192 SARS-CoV-2EscapePLEX and considered “false positive”/”false negative” when in  
27  
28 193 disagreement.

32 194 **3 Results**

35 195 3.1 Characteristics of the study population

36 196 A total of 163 participants were enrolled in the study, consisting of 45.16% (70/163)  
37  
38  
39 197 males and 54.84% (85/163) females; the median [IQR] age was 37 [28-49] years (min=2;  
40  
41 198 max=82); and 30% (49/163) of the study population reported a COVID-19 related symptom.  
42  
43  
44 199 Half of the study population had a PCR Ct-value below 19 [16-23] cycles (min=9; max=33.5).

47 200 3.2 Sanger sequencing assay performance

48  
49 201 Out of the 163 positive nasopharyngeal specimens processed, 88.96 % (145/163) were  
50  
51 202 successfully amplified after RT-PCR. Regarding sequencing (by use of the Sanger method),  
52  
53  
54 203 130 Spike-sequences were successfully generated out of the 145 processed (89.65 %), giving  
55  
56 204 an overall sequencing performance of 79.75% (130/163) [72.76-85.64] (95%CI).

205 3.3 SARS-CoV-2 Genetic diversity and lineage dynamics

1 206 According to the local SARS-CoV-2 molecular epidemiology, variants were found in  
2  
3  
4 207 91(70 %) of 130 sequences. The dynamic of SARS-CoV-2 (Figure 1) during wave-1 (April-  
5  
6 208 November 2020) showed 97% (30/31) wild-type lineages and 3% (1/31) Gamma-variant;  
7  
8 209 wave-2 (December 2020-May 2021) showed 25% (4/16) Alpha-variant, 25% (4/16) Beta-  
9  
10  
11 210 variant, 44% (7/16) wild-type lineages and 6% (1/16) mu; wave-3 (June-October 2021)  
12  
13 211 showed 93% (27/29) Delta-variant, 3.5% (1/29) Alpha-variant, 3.5% (1/29) wild-type  
14  
15  
16 212 lineages; wave-4 (November 2021-August 2022) showed 98% (53/54) Omicron-variant and  
17  
18 213 2% (1/54) Delta-variant. Omicron sub-variants were 47% (25/53) BA.1, 34% (18/53) BA.5,  
19  
20  
21 214 13% (7/53) BA.2 and 6% (3/53) BA.4.  
22  
23

24 215 Univariate analysis showed that only the Omicron variant was significantly related to  
25  
26 216 the clinical status of patients (OR=0.10[0.03-0.37]; P=0.001). The prevalence of this variant was  
27  
28  
29 217 significantly lower in symptomatic patients (p=0.01) (Table 1).  
30  
31

32 218 3.4 *Clinical performance of SNP-EscapePLEX assay*

33 219 The profile of each reported viral strain was not statistically significantly different  
34  
35  
36 220 between the two methods used – Sequencing vs. EscapePLEX, indicating possible  
37  
38  
39 221 interchangeability of these variant screening assays (Table 2).  
40  
41

42 222 Overall sensitivity and specificity of SNP-ESCAPLEX was 84% [78-87] and 89% [76-  
43  
44 223 95] respectively, which fall within the range of an acceptable performance in accuracy for the  
45  
46  
47 224 detection of COVID-19 variants in circulation (Table 3).  
48

49 225 According to viral strains, the sensitivity and specificity of SNP-Escaplex on Delta-  
50  
51 226 variant was 75% [63-76] and 100% [96-100] respectively; the sensitivity and specificity of  
52  
53  
54 227 SNP-Escaplex on Omicron-variants was 96% [90-96] and 100% [93-100] respectively  
55  
56  
57 228 respectively, indicating a very high accuracy in detecting Omicron from other pre-existing  
58  
59 229 SARS-CoV-2 variants (Table 4).  
60  
61

1  
2  
3 **4 Discussion**

4  
5 232 The rapid emergence of SARS-CoV-2 variants requires immediate deployment of  
6  
7  
8 233 surveillance tools. Rapid detection of these variants is essential as their spread may have an  
9  
10 234 impact on transmission rates, diagnostic procedures, disease severity, or vaccine response. To  
11  
12 235 date, the monitoring of the occurrence and circulation of VOCs is almost exclusively done by  
13  
14  
15 236 NGS (Bhojar et al., 2021; Chiara et al., 2021). This can be a huge constraint for global  
16  
17 237 surveillance of SARS-CoV2 mutants, as the equipment and trained personnel to perform NGS  
18  
19  
20 238 are not widely available, particularly in resource-limited settings (RLS). Although it has not  
21  
22 239 yet been licensed for identifying new variants, the SNPsig® SARS-CoV-2 kit (EscapePlex) is  
23  
24  
25 240 a rapid and cost-effective mean to discriminate between one of the previously characterised  
26  
27 241 SARS-CoV2 variants. This study allowed us to assess the molecular epidemiology of VOCs,  
28  
29  
30 242 and then, in comparison to the Sanger sequencing result, to validate the performance of the  
31  
32 243 SNPescaPLEX kit for rapid VOC screening nationwide.

33  
34  
35 244 The majority of our study population were asymptomatic (70%; 114/163), even in  
36  
37 245 advent of omicron variant, which was found in this study to be very infectious but inversely  
38  
39  
40 246 proportional with symptomatology and thus disease severity. A previous study conducted in  
41  
42 247 Cameroon observed a similar clinical profile, reporting specifically 4% of symptomatic  
43  
44  
45 248 patients (Fainguem et al., 2022). Other reports of studies conducted in different settings  
46  
47 249 confirmed that the virus can infect without causing clinical manifestations (Oran and Topol,  
48  
49  
50 250 2020;Meo et al., 2021).

51  
52  
53 251 In the analysis of the molecular epidemiology of SARS-CoV-2, Sanger genotyping  
54  
55 252 allowed us to detect all VOCs in Cameroon, including Alpha, Beta, Gamma, Delta. Regarding  
56  
57  
58 253 the dynamics of VOC occurrence (Figure 1), the first epidemiological wave is characterised by a  
59  
60 254 massive circulation of the lineage of origin. Gamma-VOC was identified in only one strain during this

255 period, suggesting that community transmission had not occurred in the country with this particular  
1  
2 256 VOC, or the sample size was not representative. In the second wave we observe the appearance of the  
3  
4 257 Alpha and Beta variants in co-circulation with the wild lineage. In the third wave we observe strong  
5  
6 258 circulation of the Delta variant, with a significant decrease in the prevalence of the Alpha variant  
7  
8 259 (3.5%). In the fourth wave, corresponding to the current wave, Omicron variant predominates at about  
9  
10 260 100%. This epidemiological profile observed in Cameroon since the beginning of the pandemic  
11  
12 261 corresponds to that observed in several other countries of the world(Afrin et al., 2022; Eales et al.,  
13  
14 262 2022; Fujino et al., 2021). The SARS-CoV-2 Omicron variant of concern (1 B.1.1.529), which became  
15  
16 263 dominant in many countries in early 2022, comprises several sub-variants. In our context, in the first  
17  
18 264 quarter (January-March 2022) the BA.1 sub-variant was the only one in circulation (100%). This was  
19  
20 265 quickly replaced by the sub-variants BA.2 at 75% (3/4) and BA.4 at 25% (1/4) in the second quarter  
21  
22 266 (April-June 2022). In the third quarter, we observe the appearance of the BA.5 sub-variant (75%)  
23  
24 267 which co-circulates mostly with BA.2 and BA.4. These results are still in line with the European  
25  
26 268 epidemiological profile, which is driven by the BA.4 and BA.5 sub-variants (ECDC, 2022). This  
27  
28 269 profile also reveals the absence of other omicron sub-variants such as BA.3 and recombinant  
29  
30 270 forms in our context, probably suggesting a low efficacy of the primers used for these sub-  
31  
32 271 lineages and sub-variants (Tegally et al., 2022).  
33  
34  
35  
36  
37  
38

39 272 Overall, Sanger sequencing demonstrated a success rate of approximately 79.75%  
40  
41 273 (130/163). A similar result was obtained previously, reporting an estimated overall  
42  
43 274 sequencing success rate of 85.1% (166/195) and suggested that low viremia is likely to be  
44  
45 275 associated with sequence failure using the Sanger approach (Jørgensen et al., 2021); calling  
46  
47 276 thus for these patients, to implement more sensitive sequencing methods such as the NGS –  
48  
49 277 with the advantage of enabling whole genome sequencing for better appreciation of viral  
50  
51 278 diversity.  
52  
53  
54  
55  
56

57 279 When comparing the two methods (EscaPLEX versus Sanger), the prevalence rates of  
58  
59 280 each variant were not significant ( $P>0.05$ ) (Table3). However, as opposed to Sanger  
60  
61  
62  
63  
64  
65

281 sequencing, EscaPLEX could not identify the Gamma, implying potential low effectiveness of  
1  
2 282 this new kit in detecting certain VOC as observed in a study in Burkina Faso, where the  
3  
4  
5 283 frequency of the Beta variant (56.6%) analysed with the SNPsig® SARS-CoV-2 kit  
6  
7 284 (EscapePlex) was lower than with the SNPsig® VariPLEX™ kit (75.6%)(Soubeiga et al.,  
8  
9  
10 285 2022). As an alternative to sequencing, the SNP\_SARSCoV-2-EscapePLEX Kit has received much  
11  
12 286 attention as a genotyping test for the rapid detection and identification of SARS-CoV-2 VOCs  
13  
14 287 (Chaintoutis et al., 2021; Umair et al., 2022). Overall, for its ability to discriminate between variants  
15  
16 288 and wild-type strains, our analyses show that the SNP\_SARSCoV-2-EscapePLEX kit has high  
17  
18 289 sensitivity (84% [78-87]) and specificity (89% [76-95]), and would be suitable for preliminary  
19  
20 290 identification of VOC in Cameroon. In terms of its ability to discriminate each SARSCoV-2 variant,  
21  
22  
23 291 this kit demonstrated good concordance with sequencing ( $K_a = 0.97$  [0.93-0.98]) and a better ability to  
24  
25 292 discriminate the Omicron variant with a sensitivity of 96% [93-98]. This result is in line with the  
26  
27 293 manufacturer's finding of 100% sensitivity for the identification of the omicron-specific K417N  
28  
29  
30 294 mutation according to the interpretation algorithm (PRIMER DESIGN, 2022). However, in  
31  
32 295 comparison to sequencing, our analysis reveals a zero sensitivity (0%) for the detection of the Gamma  
33  
34 296 variant. This result is also in agreement with the manufacturer who found a null sensitivity for the  
35  
36 297 identification of K417N (which, in association with E484K mutation confirms infection by a Gamma  
37  
38 298 variant; see table2). This finding therefore advocates for an improvement of the clinical performance  
39  
40 299 of the kit in order to fit to the molecular epidemiology within the country; enabling quick detection,  
41  
42  
43 300 and subsequent adequate response to circulating VOCs.  
44  
45

## 5 Conclusion

301  
46  
47  
48  
49 302 There is a rapid change in the molecular epidemiology of SARS-CoV-2 in Cameroon,  
50  
51  
52 303 moving from wild-type lineages to Omicron variants and sub-variants. This evidence  
53  
54 304 underscores the need for genomic surveillance to support the pandemic control strategy. For  
55  
56  
57 305 the rapid detection of viral clades, SNPsig SARSCoV-2 EscapePLEX kit is suitable in  
58  
59 306 identifying VOC circulating in RLS within simple PCR facilities available in several molecular  
60  
61  
62  
63  
64  
65

307 biology laboratories in RLS. With the emergence of Omicron sub-variants, rapid variant  
308 detection tools should be upgraded to distinguish between sub-variants.

### 309 **Ethics considerations**

310 Ethical approval was obtained from the Cameroon National Ethics Committee for research  
311 on human health (2022/01/1430/CE/CNERSH/SP), within the frame of the EDCTP (European and  
312 Developing 358 Countries Clinical Trials Partnership) PERFECT-Study (RIA2020-EF3000). A  
313 study information sheet was provided to each individual, and a written informed consent was obtained  
314 from all study participants. Confidentiality was ensured by the use of unique identifiers and data were  
315 kept in a password encrypted computer with limited access. Results were returned free of charge to  
316 each participant for a direct benefits on their clinical conditions with regards to COVID-19 infection.

### 317 **Credit authorship contribution statement**

318 **Conceptualized and initiated the manuscript :** Joseph Fokam, Desire Takou; Yap Boum II,  
319 Ezechiel Ngoufack Jagni Semengue, Vittorio Colizzi, Carlo-Federico Perno, Nicaise Ndembi,  
320 Davy-Hyacinthe Anguechia Gouissi. **Collected and Analysed the data:** Davy-Hyacinthe  
321 Anguechia gouissi, Ezechiel Ngoufack Jagni Semengue, Collins Chenwi, Grace Beloumou,  
322 Sandrine Djupsa, Alex Durand Nka, Willy Pabo, Aissatou Abba, Aude Christelle Ka'e,

504 **Table 1:** Univariate analysis of biological and clinical characteristics and SARSCoV-2  
 505 variants Of Concern.

Variant	Clinical status		OR (IC95%)	P-Value
	Asymptomatic	Symptomatic		
Lineage of origin	24	15	1	
Alpha	3(60%)	2(40%)	1.11[0.16-7.40]	0.91
Beta	1(33.33%)	2(66.66%)	3.33[0.28-39.01]	0.34
Gamma	0	1(100%)	--	--
Delta	17(60.71%)	11(39.28%)	1.08[0.40-8-2.90]	0.87
Omicron	50(94.33%)	3(05.67%)	0.10[0.03-0.37]	0.001

506  
 507 **Table 2:** SARS-CoV-2 Variant and Lineage of origin detected using Sanger sequencing and  
 508 SNP- ExcaPLEX kits.

VOCs	Sanger sequencing	SNP- ExcaPLEX	P-Value
Wild-type	30.00 (39/130)	35.38 (46/130)	0.35
Alpha	3.85(5/130)	6.92 (9/130)	0.24
Beta	2.31(3/130)	2.31 (3/130)	1.00
Gamma	0.77(1/130)	0.00 (0/130)	0.32
Mu	0.77(1/130)	0.00 (0/130)	0.32
Delta	21.54(28/130)	16.15 (21/130)	0.26
Omicron	40.77(53/130)	39.23(51/130)	0.80

521 **Table 3:** Clinical Performance of SNPsig SARS-CoV-2 EscapePLEX

		Sequencing result		
		Sars-cov-2 Variant	Ligneage of origine	Total
<b>SNP-EscapePLEX)</b>	Sars-cov-2 Variant	78	4	82
	Ligneage of origine	15	33	48
	Total	93	37	130
	Sensitivity (Se)=84% [78-87]; Sp=89% [76-95]; Ka(Kappa)= 0.67 [0.51-0.76]			

530 **Table4:** Intrinsic features of RT-PCR genotyping Kit

<b>SNP-EscapePLEX</b>		<b>Spike-genome sequencing</b>	
<b>(A) Alpha-variant vs Non Alpha</b>			
		<i>Alpha</i>	<i>Non Alpha</i>
<i>Alpha</i>		78	4
<i>Non Alpha-</i>		15	33
<i>Se=84% [78-86]; Sp=89% [76-96]; PPV=95% [89-98] ; NVP=69% [59-74] Ka= 0.67 [0.51-0.76]</i>			
<b>(B) Beta-variant vs Non Beta</b>			
		<i>Beta</i>	<i>Non Beta</i>
<i>Beta</i>		2	2
<i>Non Beta</i>		1	125
<i>Se=67% [14-97]; Sp=98% [97-99]; PPV=50% [10-76] ; NVP=99% [97-1000] Ka= 0.56 [0.09-0.83]</i>			
<b>(C) Gamma-variant vs Non Gamma</b>			
		<i>Gamma</i>	<i>Non Gamma</i>
<i>Gamma</i>		0	0
<i>Non Gamma</i>		1	129
<i>Se=0% ; Sp=100%</i>			
<b>(D) Delta-variant vs Non Delta</b>			
		<i>Delta</i>	<i>Non Delta</i>
<i>Delta</i>		21	0
<i>Non Delta</i>		7	102
<i>Se=75% [63-75] ; Sp=100% [96-100]; PPV=100% [84-100]; NVP=94% [74-94] Ka= 0.82 [0.65-0.83]</i>			
<b>(E) Omicron-variant vs Non Omicron</b>			
		<i>Omicron</i>	<i>Non Omicron</i>
<i>Omicron</i>		51	0
<i>Non Omicron</i>		2	77
<i>Se=96% [93-98]; Sp=100% [95-100]; PPV=100% [94-100] ; NVP=97% [95-100] Ka= 0.97 [0.93-0.98]</i>			
<i>Se=Sensitivity; Sp= Specificity; PPV= Positive Predictive Value; NPV= Negative Predictive Value</i>
